(54) Title: PROSTAGLANDIN ENDOPEROXIDE H SYNTHASE BIOSYNTHESIS INHIBITORS (57) Abstract The present invention describes pyridazinone compounds which are cyclooxygenase (COX) inhibitors, and in particular, are selective inhibitors of cyclooxygenase-2 (COX-2). COX-2 is the inducible isoform associated with inflammation, as opposed to the constitutive isoform, cyclooxygenase-1 (COX-1) which is an important "housekeeping" enzyme in many tissues, including the gastrointestinal (GI) tract and the kidneys. The selectivity of these compounds for COX-2 minimizes the unwanted GI and renal side-effects seen with currently marketed non-steroidal anti-inflammatory drugs (NSAIDs).

PROSTAGLANDIN ENDOPEROXIDE H SYNTHASE BIOSYNTHESIS INHIBITORS

Technical Field

The present invention encompasses novel pyridazinone compounds useful
5 in the treatment of cyclooxygenase-2 mediated diseases. More particularly, this
invention concerns a method of inhibiting prostaglandin biosynthesis, particularly
the induced prostaglandin endoperoxide H synthase (PGHS-2, cyclooxygenase-2,
COX-2) protein.

Background of the Invention

10 The prostaglandins are extremely potent substances which produce a wide
variety of biological effects, often in the nanomolar to picomolar concentration
range. The discovery of two forms of prostaglandin endoperoxide H synthase,
isozymes PGHS-1 and PGHS-2, that catalyze the oxidation of arachidonic acid
leading to prostaglandin biosynthesis has resulted in renewed research to
15 delineate the role of these two isozymes in physiology and pathophysiology.
These isozymes have been shown to have different gene regulation and represent
distinctly different prostaglandin biosynthesis pathways. The PGHS-1 pathway is
expressed constitutively in most cell types. It responds to produce prostaglandins
that regulate acute events in vascular homeostasis and also has a role in
20 maintaining normal stomach and renal function. The PGHS-2 pathway involves an
induction mechanism which has been linked to inflammation, mitogenesis and
ovulation phenomena.

Prostaglandin inhibitors provide therapy for pain, fever, and inflammation,
and are useful therapies, for example in the treatment of rheumatoid arthritis and
25 osteoarthritis. The non-steroidal anti-inflammatory drugs (NSAIDs) such as
ibuprofen, naproxen and fenamates inhibit both isozymes. Inhibition of the
constitutive enzyme PGHS-1 results in gastrointestinal side effects including ulcers
and bleeding and incidence of renal problems with chronic therapy. Inhibitors of
the induced isozyme PGHS-2 may provide anti-inflammatory activity without the
30 side effects of PGHS-1 inhibitors.

The problem of side-effects associated with NSAID administration has never
completely been solved in the past. Enteric coated tablets and co-administration
with misoprostol, a prostaglandin derivative, have been tried in an attempt to
minimize stomach toxicity. It would be advantageous to provide compounds which
35 are selective inhibitors of the induced isozyme PGHS-2.

The present invention discloses novel compounds which are selective inhibitors of PGHS-2.

Preparation of Compounds of the Invention

25 The compounds of the invention may be prepared by a variety of synthetic routes. Representative procedures are outlined in Scheme 1 below.

A general route to the compounds of the invention having Formula III, where the aryl group at the 5-position on the pyridazinone ring is substituted with a sulfonyl group ring (R^2 is aminosulfonyl, or methylsulfonyl, shown as methylsulfonyl) is described in Scheme 1, below. Phenyl acetic acid, optionally substituted, was
30 condensed with a benzaldehyde to form the corresponding 2-phenyl-*trans*-cinnamic acid. The *trans*-cinnamic acid was converted to the corresponding acid chloride which was then decarbonylated to provide the benzyl-aryl ketone. The ketone was

then alkylated with ethyl bromoacetate in the presence of a strong base such as sodium bis(trimethylsilyl)amide. Treatment of the ketoester product with hydrazine, in an alcohol solvent, such as ethanol, provided dihydropyridazinone. The dihydropyridazinone was dehydrogenated to form the pyridazinone by treatment with
5 Bromine in acetic acid. If desired, the R' group can be added via substitution using an appropriate alkylating agent. In Scheme 1, X is defined as in R³ and R' is defined as in R.

The term "prodrug" refers to compounds that are rapidly transformed *in vivo* to provide the parent compound having the above formula, for example by hydrolysis in blood. A thorough discussion is provided in T. Higuchi and V. Stella, Pro-drugs as Novel Delivery Systems, Vol. 14 of the A.C.S. Symposium Series, and in Edward B. Roche, ed., Bioreversible Carriers in Drug Design, American Pharmaceutical Association and Pergamon Press, 1987, both of which are incorporated herein by reference.

As used throughout this specification and the appended claims, the term metabolically cleavable group denotes a moiety which is readily cleaved *in vivo* from the compound bearing it, wherein said compound, after cleavage remains or becomes pharmacologically active. Metabolically cleavable groups form a class of groups reactive with the carboxyl group of the compounds of this invention are well known to practitioners of the art. They include, but are not limited to groups such as, for example, alkanoyl, such as acetyl, propionyl, butyryl, and the like; unsubstituted and substituted aroyl, such as benzoyl and substituted benzoyl; alkoxycarbonyl, such as ethoxycarbonyl; trialkylsilyl, such as trimethyl- and triethysilyl; monoesters formed with dicarboxylic acids, such as succinyl, and the like. Because of the ease with which the metabolically cleavable groups of the compounds of this invention are cleaved *in vivo*, the compounds bearing such groups act as pro-drugs of other prostaglandin biosynthesis inhibitors. The compounds bearing the metabolically cleavable groups have the advantage that they may exhibit improved bioavailability as a result of enhanced solubility and/or rate of absorption conferred upon the parent compound by virtue of the presence of the metabolically cleavable group.

Asymmetric centers may exist in the compounds of the present invention. The present invention contemplates the various stereoisomers and mixtures thereof. Individual stereoisomers of compounds of the present invention are made by synthesis from starting materials containing the chiral centers or by preparation of mixtures of enantiomeric products followed by separation as, for example, by conversion to a mixture of diastereomers followed by separation by recrystallization or chromatographic techniques, or by direct separation of the optical enantiomers on chiral chromatographic columns. Starting compounds of particular stereochemistry are either commercially available or are made by the methods detailed below and resolved by techniques well known in the organic chemical arts.

Prostaglandin Inhibition Determination

Compound Preparation and Administration

For oral administration, test compounds were suspended on the day of use
5 in 100% polyethyleneglycol (PEG 400) with a motorized homogenizer equipped
with a Teflon-coated pestle (TRI-R Instrument, Jamaica, NY).

To compare the mean responses of the treatment groups, analysis of
variance was applied. Percent inhibition values were determined by comparing
the individual treatment mean values to the mean of the control group. Linear
10 regression was used to estimate IC₅₀'s/ED₅₀'s in appropriate assays.

EIA Determination of Prostaglandins

EIA reagents for prostaglandin determination were purchased from
Perseptive Diagnostics, (Cambridge, MA). PGE₂ levels in lavage fluids were
determined after the samples were dried under nitrogen and reconstituted with
15 assay buffer. PGE₂ levels in enzyme assays or cell culture media were measured
against standards prepared in the same milieu. The immunoassays were
conducted as recommended by the manufacturer. The EIA was conducted in 96
well microtiter plates (Nunc Roskilde, Denmark) and optical density was measured
using a microplate reader (Vmax, Molecular Devices Corp., Menlo Park, CA).

20 Recombinant Human PGHS-1 and PGHS-2 Enzyme Assays

Inhibition of prostaglandin biosynthesis *in vitro* was evaluated using
recombinant human Cox-1 (r-hu Cox1) and Cox-2 (r-hu Cox2) enzyme assays.
Representative compounds dissolved in DMSO (3.3% v/v) were preincubated with
microsomes from recombinant human Cox-1 or Cox-2 expressed in the
25 baculovirus/Sf9 cell system (Gierse, J. K., Hauser, S. D., Creely, D. P., Koboldt, C.,
Rangwala, S., H., Isakson, P. C., and Seibert, K. Expression and selective
inhibition of the constitutive and inducible forms of cyclooxygenase, *Biochem J.*
1995, 305: 479.), together with the cofactors phenol (2 mM) and hematin (1 μ M) for
60 minutes prior to the addition of 10 μ M arachidonic acid. The reaction was

- allowed to run for 2.5 minutes at room temperature prior to quenching with HCl and neutralization with NaOH. PGE₂ production in the presence and absence of the drug was determined by EIA analysis. The EIA was conducted in 96 well microtiter plates (Nunc Roskilde, Denmark) and optical density was measured using a
- 5 microplate reader (Vmax, Molecular Devices Corp., Menlo Park, CA). EIA reagents for prostaglandin determination were purchased from Perseptive Diagnostics (Cambridge, MA). PGE₂ levels were measured against standards prepared in the same milieu. The immunoassays were conducted as recommended by the manufacturer.
- 10 The data illustrating the inhibition of prostaglandin biosynthesis *in vitro* by compounds of this invention is shown in Table 1. The compounds are designated by the Example Number. Column 2 shows Cox-1 percent inhibition at the particular micromolar dose level. Column 3 shows Cox-2 percent inhibition at the particular nanomolar dose level. Values for Cox-2 inhibition that are parenthetical
- 15 indicate IC₅₀ values.

IL-1 β Induced PGE₂ Production in WISH Cells

Human amnionic WISH cells were grown to 80% confluence in 48 well plates. Following removal of the growth medium and two washings with Gey's
 5 Balanced Salt Solution, 5 ng IL-1 β /ml (UBI, Lake Placid, NY) was added to the cells with or without test compound in DMSO (0.01% v/v) in Neuman-Tytell Serumless Medium (GIBCO, Grand Island, NY). Following an 18 hour incubation to allow for the maximal induction of PGHS-2, the conditioned medium was removed and assayed for PGE₂ activity by EIA analysis as described above.

10 U937 (ATCC, Rockville, MD) cells were grown in a similar fashion to the WISH cells. After incubation, the conditioned medium was removed and assayed for Cox-1 activity by EIA analysis as described above.

The data illustrating the inhibition of prostaglandin biosynthesis *in vitro* by compounds of this invention is shown in Table 2. U937 values indicate percent
 15 inhibition at the particular micromolar dose level while parenthetical values indicate IC₅₀ values. Wish cell values indicate Cox-2 percent inhibition at the particular micromolar dose level.

Carrageenan Induced Paw Edema (CPE) in Rats

Hindpaw edema was induced in male rats as described by Winter *et al.*,
5 *Proc. Soc. Exp. Biol. Med.*, **1962**, 111, 544. Briefly, male Sprague-Dawley rats
weighing between 170 and 190 g were administered test compounds orally 1 hour
prior to the subplantar injection of 0.1 ml of 1% sodium carrageenan (lambda
carrageenan, Sigma Chemical Co., St Louis, MO) into the right hindpaw. Right
paw volumes (ml) were measured immediately following injection of carrageenan
10 for baseline volume measurements using a Buxco plethysmograph (Buxco
Electronics, Inc., Troy, NY). Three hours after the injection of carrageenan, right
paws were remeasured and paw edema calculated for each rat by subtracting the
zero time reading from the 3 hour reading. Data are reported as mean percent
inhibition +/- SEM. Statistical significance of results was analyzed by Dunnetts
15 multiple comparison test where $p < 0.05$ was considered statistically significant.

Rat Carrageenan Pleural Inflammation Model (CIP)

Pleural inflammation was induced in male adrenalectomized Sprague-Dawley rats following the method of Vinegar *et al.*, *Fed. Proc.* 1976, 35, 2447-2456. Animals were orally dosed with experimental compounds, in 0.2% HPMC, 30 minutes prior to the intrapleural injection of 2% lambda carrageenan (Sigma Chemical Co., St. Louis MO). Four hours later the animals were euthanized and the pleural cavities lavaged with ice cold saline. The lavage fluid was then added to two volumes of ice cold methanol (final methanol concentration 66%) to lyse cells and precipitate protein. Eicosanoids were determined by EIA as described above. The data illustrating the inhibition of prostaglandin biosynthesis *in vivo* by the compounds of this invention is shown in Table 3. Values reported are percent inhibition at 10 milligrams per kilogram body weight.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethylformamide, oils (such as, for example, cottonseed, groundnut, corn, germ, olive, castor, sesame oils, and the like), glycerol, tetrahydrofurfuryl alcohol, poly-ethyl-ene glycols and fatty acid esters of sorbitan, and mixtures thereof. Besides inert diluents, the oral compositions can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

25 Injectable preparations, such as, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution, suspension or emulsion in a nontoxic parenterally acceptable diluent or solvent, such as, for example, a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, isotonic sodium chloride solution, and the like. In addition, sterile, fixed oils are conventionally

30

employed as a solvent or suspending medium. For this purpose any bland fixed oil can be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid are used in the preparation of injectable preparations.

The injectable formulations can be sterilized by any method known in the art, such as, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions which can be dissolved or dispersed in sterile water or other sterile injectable medium prior to use.

In order to prolong the effect of a drug, it is often desirable to slow the absorption of the drug from subcutaneous or intramuscular injection. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the drug then depends upon its rate of dissolution which, in turn, may depend upon crystal size and crystalline form. Alternatively, delayed absorption of a parenterally administered drug form is accomplished by dissolving or suspending the drug in an oil vehicle. Injectable depot forms are made by forming microencapsulated matrices of the drug in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of drug to polymer and the nature of the particular polymer employed, the rate of drug release can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and poly(anhydrides). Depot injectable formulations are also prepared by entrapping the drug in liposomes or microemulsions which are compatible with body tissues.

Compositions for rectal or vaginal administration are preferably suppositories which can be prepared by mixing the compounds of this invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax which are solid at ambient temperature but liquid at body temperature and thus melt in the rectum or vaginal cavity and release the active compound.

Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is usually mixed with at least one inert, pharmaceutically acceptable excipient or carrier such as, for example, sodium citrate or dicalcium phosphate and/or a) fillers

or extenders such as, for example, starches, lactose, sucrose, glucose, mannitol, and silicic acid, b) binders such as, for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidinone, sucrose, and acacia, c) humectants such as, for example, glycerol, d) disintegrating agents such as, for example, agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as, for example, paraffin, f) absorption accelerators such as, for example, quaternary ammonium compounds, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as, for example, kaolin and bentonite clay, and) lubricants such as, for example, talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. In the case of capsules, tablets and pills, the dosage form may also comprise buffering agents.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients such as, for example, lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using excipients such as, for example, lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

The active compounds can also be in micro-encapsulated form with one or more excipients as noted above. The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings, release controlling coatings and other coatings well known in the pharmaceutical formulation art. In such solid dosage forms the active compound may be admixed with at least one inert diluent such as, for example, sucrose, lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., tableting lubricants and other tableting aids such as, for example, magnesium stearate and microcrystalline cellulose. In the case of capsules, tablets and pills, the dosage forms may also comprise buffering agents. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed

manner. Examples of embedding compositions which can be used include polymeric substances and waxes.

Dosage forms for topical or transdermal administration of a compound of this invention include ointments, pastes, creams, lotions, gels, powders, solutions, 5 sprays, inhalants or patches. The active component is admixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives or buffers as may be required. Ophthalmic formulation, ear drops, eye ointments, powders and solutions are also contemplated as being within the scope of this invention.

10 The ointments, pastes, creams and gels may contain, in addition to an active compound of this invention, excipients such as, for example, animal and vegetable fats, oils, waxes, paraffins, starch, tragacanth, cellulose derivatives, polyethylene glycols, silicones, bentonites, silicic acid, talc and zinc oxide, or mixtures thereof.

Powders and sprays can contain, in addition to the compounds of this 15 invention, excipients such as, for example, lactose, talc, silicic acid, aluminum hydroxide, calcium silicates and polyamide powder, or mixtures of these substances. Sprays can additionally contain customary propellants such as chlorofluorohydrocarbons.

Transdermal patches have the added advantage of providing controlled 20 delivery of a compound to the body. Such dosage forms can be made by dissolving or dispensing the compound in a suitable medium. Absorption enhancers can also be used to increase the flux of the compound across the skin. The rate can be controlled by either providing a rate controlling membrane or by dispersing the compound in a polymer matrix or gel.

25 According to the methods of treatment of the present invention, a patient, such as a human or mammal, is treated by administering to the patient a therapeutically effective amount of a compound of the invention, in such amounts and for such time as is necessary to achieve the desired result. By a "therapeutically effective amount" of a compound of the invention is meant a 30 sufficient amount of the compound to provide the relief desired, at a reasonable benefit/risk ratio applicable to any medical treatment. It will be understood, however, that the total daily usage of the compounds and compositions of the

present invention will be decided by the attending physician within the scope of sound medical judgment. The specific therapeutically effective dose level for any particular patient will depend upon a variety of factors including the disorder being treated and the severity of the disorder; the activity of the specific compound employed; the specific composition employed; the age, body weight, general health, sex and diet of the patient; the time of administration, route of administration, and rate of excretion of the specific compound employed; the duration of the treatment; drugs used in combination or coincidental with the specific compound employed; and like factors well known in the medical arts.

- 10 The total daily dose of the compounds of this invention administered to a human or other mammal in single or in divided doses can be in amounts, for example, from 0.001 to about 1000 mg/kg body weight daily or more preferably from about 0.1 to about 100 mg/kg body weight for oral administration or 0.01 to about 10 mg/kg for parenteral administration daily. Single dose compositions may contain such
15 amounts or submultiples thereof to make up the daily dose.

The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration.

- The reagents required for the synthesis of the compounds of the invention
20 are readily available from a number of commercial sources such as Aldrich Chemical Co. (Milwaukee, WI, USA); Sigma Chemical Co. (St. Louis, MO, USA); and Fluka Chemical Corp.
